Abstract

A covariant version of the non-abelian Dirac-Born-Infeld-Myers action is presented. The non-abelian degrees of freedom are incorporated by adjoining to the (bosonic) worldvolume of the brane a number of anticommuting fermionic directions corresponding to boundary fermions in the string picture. The proposed action treats these variables as classical but can be given a matrix interpretation if a suitable quantisation prescription is adopted. After gauge-fixing and quantisation of the fermions, the action is shown to be in agreement with the Myers action derived from T-duality. It is also shown that the requirement of covariance in the above sense leads to a modified WZ term which also agrees with the one proposed by Myers.

1 Introduction

An intriguing feature of string theory is the fact that one can have coincident D-branes. The lowest-order action for such stacks of branes includes the Yang-Mills action for the non-abelian gauge fields which arise when one takes the coincidence limit. Since the gauge part of the action for a single D-brane is Born-Infeld one would expect that a non-abelian generalisation of this action should be required in the case of coincident branes. Although there has been a lot of work on this topic it is still not completely clear what this action is and how it should incorporate invariance principles. It is the purpose of this note to propose such an action for both the Dirac-Born-Infeld and the WZ terms which should be present. The derivation we give is strictly speaking only valid in a certain approximation, which we explain below, but we shall argue that it is not unreasonable to expect that it can be extended beyond this.

Many features of the bosonic terms in the non-abelian action are known. Some years ago, Tseytlin [1] put forward the proposal that the ordinary Born-Infeld action could be generalised to the non-abelian case by using the same formula with an overall symmetrised trace. Although this does not incorporate all the terms in the effective string action [2] it is nevertheless a well-defined object to work with. Subsequently, starting from the Tseytlin action, Myers derived a non-abelian Dirac-Born-Infeld action by demanding that lower-dimensional brane actions be consistent with T-duality [3]. He also used T-duality to derive a non-abelian Wess-Zumino term and showed that this has the property that higher degree RR forms can couple to a Dp -brane giving rise to a dielectric effect. Similar results were obtained from matrix theory [4, 5]. We shall show that Myers's results can be understood from the point of view of invariance under diffeomorphisms of the brane and gauge symmetries.

The Myers version of the DBI action was derived in the physical gauge where $(p+1)$ of the coordinates of the target space are identified with those of the brane and the transverse coordinates are taken to be the scalar fields. These are then promoted to matrices in the non-abelian theory. This procedure clearly breaks diffeomorphism symmetry for the brane. Although non-abelian gauge invariance is maintained through the use of covariantised pull-backs it is not at all obvi-

ous that the Myers action is invariant with respect to gauge transformations of the background gauge fields. This is also true for the Wess-Zumino term which involves the RR potentials as well as the B field. In fact, it is not clear what the non-abelian generalisation of the modified field strength which appears in the action for a single D-brane should be. A proposal for this was made in [6] in the supersymmetric context and this is the one which we shall use here.

In this paper we shall derive non-abelian DBI and WZ actions in a formalism which is inspired by the use of boundary fermions to describe non-abelian degrees of freedom in open string theory [7, 8, 9, 10]. We shall work in the approximation in which these fermions are taken to be classical variables. Mathematically this amounts to extending the worldvolume of the brane by a number of fermionic directions and replacing the brane embedding in the target spacetime by a generalised embedding defined as a map from the extended worldvolume to the target space [6]. Although the formalism is not a fully-fledged matrix formalism, the results we derive can be compared to those in the literature if we replace the Poisson bracket (in the fermionic part of the space) by the matrix commutator and impose the symmetrised trace prescription. This approach can be justified to some extent in the world-sheet picture. In the papers cited above it is shown how quantisation of the fermions leads to the fermions being replaced by gamma matrices, so that functions of them become matrices, and how correlation functions of products of operators involving the fermions become the path-ordered trace of products of matrices. Since we are concerned with operators at the same boundary point it is natural to adopt the prescription that the path-ordered trace goes over to the symmetrised trace in this case. Moreover, it is canonical practice to replace Poisson brackets by commutators in the quantisation procedure.

The DBI action we propose has a very simple structure. Since the extended space is actually a superspace it is natural to replace the Born-Infeld determinant with a superdeterminant. The matrix in this superdeterminant is the sum of the pull-back of the target space metric and an abelian two-form field strength modified by the pull-back of the B -field. The non-abelian gauge field emerges from the expansion of the abelian gauge field in the fermionic coordinates. This action is manifestly invariant under diffeomorphisms and gauge transformations and we show explicitly that it reproduces the Myers DBI action in the physical gauge. Our WZ action looks very similar to the Myers WZ action. We show that the couplings of the branes to scalar commutators can be motivated by diffeomorphism invariance while the couplings to the higher rank RR forms are then required by RR gauge symmetry. However, our formalism is not manifestly invariant and one has to work to prove these results. Although the structure of our WZ action is very similar to Myers's there is a difference in that his involves contractions of forms with the scalar commutator whereas ours involves a similar contraction but in the fermionic directions. We show explicitly how the terms collect together to give the Myers result. Our conventions for differential forms are given in the appendix.

2 The geometry of $\widehat{M}$ and the non-abelian gauge field

We shall be interested in a p -brane specified by an embedding $f : M \rightarrow \underline{M}$ where M is the worldvolume of the brane and $\underline{M}$ the target space, both spaces being bosonic. In order to incorporate non-abelian degrees of freedom we extend the former to a superspace, $\widehat{M}$, the coordinates of which we denote by $y^M = (x^m, \eta^\mu)$. The coordinates of the target space are denoted by $x^{\underline{m}}$. The embedding is replaced by a generalised embedding $\widehat{f} : \widehat{M} \rightarrow \underline{M}$. The space $\widehat{M}$ is equipped with an abelian gauge field $\mathcal{A}$ such that the modified field strength

$$K := d\mathcal{A} - \hat{f}^* B , \quad (2.1)$$

where B is the NS two-form potential on the target space, is invariant under gauge transformations of both objects. It is furthermore assumed that $K_{\mu\nu}$ is non-singular.

Following the ideas developed in [6] we use the field K to specify horizontal subspaces in the tangent spaces of $\widehat{M}$. If ω is a one-form on $\widehat{M}$ then we define its horizontal component to be

$$\widehat{\omega}_m = \omega_m - K_m^\nu \omega_\nu , \quad (2.2)$$

where

$$K_m^\mu := K_{m\nu} N^{\nu\mu} \quad (2.3)$$

and

$$N^{\mu\nu} := (K_{\mu\nu})^{-1} . \quad (2.4)$$

We can view this as a change of basis if we also identify $\widehat{\omega}_\mu = \omega_\mu$. For a vector v we have

$$\begin{aligned} \widehat{v}^m &= v^m \\ \widehat{v}^\mu &= v^\mu + v^m K_m^\mu \end{aligned} \quad (2.5)$$

We define the horizontal component of K itself to be $\mathcal{F}$,

$$\mathcal{F}_{mn} := K_{mn} - K_{m\mu} N^{\mu\nu} K_{\nu n} . \quad (2.6)$$

We note that K has no mixed components in the hatted basis. It is straightforward to compute the transformation properties of various objects under diffeomorphisms. In particular, we have

$$\begin{aligned} \delta K_m^\mu &= \widehat{v}^n (\mathcal{D}_n K_m^\mu - \mathcal{D}_m K_n^\mu) + \widehat{v}^\nu \partial_\nu K_m^\mu + \mathcal{D}_m \widehat{v}^\mu - N^{\mu\nu} \partial_\nu \widehat{v}^n \mathcal{F}_{nm} \\ \delta N^{\mu\nu} &= \widehat{v}^m \mathcal{D}_m N^{\mu\nu} + \widehat{v}^\rho \partial_\rho N^{\mu\nu} - 2N^{\rho(\mu} \partial_\rho \widehat{v}^{\nu)} + 2\widehat{v}^m N^{\rho(\mu} \partial_\rho K_m^{\nu)} \end{aligned} \quad (2.7)$$

which implies that

$$\begin{aligned} \delta \widehat{\omega}_m &= \widehat{v}^n \mathcal{D}_n \widehat{\omega}_m + \widehat{v}^\nu \partial_\nu \widehat{\omega}_m + \mathcal{D}_m \widehat{v}^n \widehat{\omega}_n + N^{\mu\nu} \partial_\nu \widehat{v}^n \mathcal{F}_{nm} \widehat{\omega}_\mu \\ \delta \widehat{\omega}_\mu &= \widehat{v}^n \mathcal{D}_n \widehat{\omega}_\mu + \widehat{v}^\nu \partial_\nu \widehat{\omega}_\mu + \partial_\mu \widehat{v}^n \widehat{\omega}_n + \partial_\mu \widehat{v}^\nu \widehat{\omega}_\nu - \widehat{v}^n \partial_\mu K_n^\nu \widehat{\omega}_\nu . \end{aligned} \quad (2.8)$$

The derivative $\mathcal{D}_m$ is defined by

$$\mathcal{D}_m := \partial_m - K_m^\mu \partial_\mu . \quad (2.9)$$

The transformation rule of $\widehat{\omega}_m$ shows that this object is not preserved under general diffeomorphisms, only those for which $\partial_\mu \widehat{v}^n = 0$. Transformations which do not satisfy this constraint are needed in order to reach the physical gauge where the generalised embedding has the form

$$x^{\underline{m}} = (x^m, x^{m'}(x, \eta)) . \quad (2.10)$$

However, we do not want to make this gauge choice at this stage as the power of covariance would be lost. Note that any object which has no mixed components in the hatted basis will transform homogeneously under diffeomorphisms. This holds for $\mathcal{F}_{mn}$.

We now turn to the emergence of a non-abelian gauge field from the abelian one we have introduced. The requirement that $K_{\mu\nu}$ be non-singular will be satisfied for any background B if $(d\mathcal{A})_{\mu\nu}$ is non-singular. We can then use a vertical diffeomorphism to bring $\mathcal{A}_\mu$ to the standard form

$$\mathcal{A}_\mu = \frac{1}{2}\eta_\mu . \quad (2.11)$$

The transformations of $\mathcal{A}$ are

$$\delta\mathcal{A}_M = \partial_M a + v^N (\partial_N \mathcal{A}_M - \partial_N \mathcal{A}_N) + b_M \quad (2.12)$$

where a is the abelian gauge parameter and b_M is the pull-back of the gauge parameter for gauge transformations of the B field. As stated above we can use v^μ to go to the standard gauge for $\mathcal{A}_\mu$. The residual vertical diffeomorphisms are then given by

$$v^\mu = -\delta^{\mu\nu} (\partial_\nu a + b_\nu - v^n \partial_\nu \mathcal{A}_n) \quad (2.13)$$

We shall denote $\mathcal{A}_m$ in the standard gauge by A_m ; it transforms as

$$\delta A_m = \partial_m a + (A_m, a) + \widetilde{b}_m + v^n F_{nm} . \quad (2.14)$$

where the Poisson bracket $(,)$ is defined by

$$(f, g) := \delta^{\mu\nu} \partial_\mu f \partial_\nu g . \quad (2.15)$$

$F_{mn} := \partial_m A_n - \partial_n A_m + (A_m, A_n)$ is the non-abelian field strength tensor, and $\widetilde{b}_m$ denotes the covariant pull-back of b with respect to the Yang-Mills derivative. This is given by

$$\widetilde{b}_m := D_m x^{\underline{m}} b_{\underline{m}} = (\partial_m x^{\underline{m}} + A_m{}^\mu \partial_\mu x^{\underline{m}}) b_{\underline{m}} , \quad (2.16)$$

where

$$A_m{}^\mu := \delta^{\mu\nu} \partial_\nu \mathcal{A}_m . \quad (2.17)$$

The relation between the non-abelian field strength tensor and $\mathcal{F}$, in the standard gauge, is given by

$$\mathcal{F}_{mn} = F_{mn} - \tilde{B}_{mn} - \tilde{B}_{m\mu} N^{\mu\nu} \tilde{B}_{\nu n} . \quad (2.18)$$

This formula may be taken as the definition of the appropriately modified non-abelian field strength tensor in the presence of a B field.

For later use we note the relation between the hatted and tilded bases, valid in the standard gauge. The fermionic components of a one-form ω are the same while

$$\hat{\omega}_m = \tilde{\omega}_m + \tilde{B}_{m\mu} N^{\mu\nu} \omega_\nu . \quad (2.19)$$

3 The DBIM action

In this section we present the Lagrangian for the DBIM action in the presence of the additional fermionic variables. We set

$$L_{MN} := g_{MN} + K_{MN} \quad (3.1)$$

where g_{MN} denotes the pull-back of the target-space metric to $\widehat{M}$. The Lagrangian is then simply

$$\mathcal{L} = \sqrt{-\text{sdet } L_{MN}} . \quad (3.2)$$

This Lagrangian obviously transforms as a density under diffeomorphisms of $\widehat{M}$ and is manifestly invariant under gauge transformations of both $\mathcal{A}$ and B . We shall now show that it coincides with the Myers action [3] in the physical gauge provided that we interpret functions of η as matrices, replace Poisson brackets by commutators and replace integration over the fermionic variables with the symmetrised trace over all matrix factors.

The superdeterminant is

$$\text{sdet } L_{MN} = \det (L_{mn} - L_{m\mu} L^{\mu\nu} L_{\nu n}) (\det L_{\mu\nu})^{-1} , \quad (3.3)$$

where $L^{\mu\nu} := (L_{\mu\nu})^{-1}$. If we introduce $E_{MN} := g_{MN} - B_{MN}$, then

$$L_{mn} = E_{mn} + (dA)_{mn} \quad (3.4)$$

while

$$L_{\mu\nu} = \delta_{\mu\nu} + E_{\mu\nu} \quad (3.5)$$

and

$$L_{m\mu} = E_{m\mu} - A_{m\mu} \quad (3.6)$$

in the standard gauge, $A_\mu = \frac{1}{2}\eta_\mu$. We remind the reader that $A_{m\mu} = \partial_\mu A_m$. We therefore have

$$L_{mn} - L_{m\mu} L^{\mu\nu} L_{\nu n} = E_{mn} + (dA)_{mn} - (E_{m\mu} - A_{m\mu})(\delta_{\mu\nu} + E_{\mu\nu})^{-1}(E_{\nu n} + A_{n\nu}) . \quad (3.7)$$

We want to express this in terms of F_{mn} and replace the ordinary pull-back on m indices by the covariant one defined by $D_m = \partial_m + A_m^\mu \partial_\mu$. After a straightforward piece of algebra one indeed finds that

$$L_{mn} - L_{m\mu} L^{\mu\nu} L_{\nu n} = \tilde{E}_{mn} + F_{mn} - \tilde{E}_{m\mu}(\delta_{\mu\nu} + E_{\mu\nu})^{-1} \tilde{E}_{\nu n} , \quad (3.8)$$

where

$$\begin{aligned} \tilde{E}_{mn} &= D_m x^{\underline{m}} D_n x^{\underline{n}} E_{\underline{mn}} \\ \tilde{E}_{m\nu} &= D_m x^{\underline{m}} \partial_\nu x^{\underline{n}} E_{\underline{mn}} . \end{aligned} \quad (3.9)$$

We shall now compute the second term on the RHS of (3.8) in the physical gauge, $x^{\underline{m}} = (x^m, x^{m'}(x, \eta))$. In this gauge

$$\begin{aligned} \tilde{E}_{m\nu} &= D_m x^{\underline{m}} \partial_\nu x^{\underline{n}} E_{\underline{mn}} \\ &= D_m x^{\underline{m}} \partial_\nu x^{n'} E_{\underline{mn}'} \\ &= \partial_\nu x^{n'} (E_{mn'} + A_m^\mu \partial_\mu x^{m'} E_{m'n'}) \\ &= \tilde{E}_{mn'} \partial_\nu x^{n'} , \end{aligned} \quad (3.10)$$

while

$$E_{\mu\nu} = \partial_\mu x^{m'} \partial_\nu x^{n'} E_{m'n'} . \quad (3.11)$$

We therefore have

$$\tilde{E}_{m\mu}(\delta_{\mu\nu} + E_{\mu\nu})^{-1} \tilde{E}_{\nu n} = \tilde{E}_{mp'} \partial_\mu x^{p'} (\delta_{\mu\nu} + E_{\mu\nu})^{-1} \partial_\nu x^{q'} \tilde{E}_{q'n} . \quad (3.12)$$

Expanding out the inverse we find

$$\partial_\mu x^{p'} (\delta_{\mu\nu} + E_{\mu\nu})^{-1} \partial_\nu x^{q'} = M^{p'q'} - M^{p'r'} E_{r's'} M^{s'q'} + \dots \quad (3.13)$$

where

$$M^{m'n'} := \delta^{\mu\nu} \partial_\mu x^{m'} \partial_\nu x^{n'} = (x^{m'}, x^{n'}) . \quad (3.14)$$

The series of terms is easily summed; the final result is

$$L_{mn} - L_{m\mu} L^{\mu\nu} L_{\nu n} = F_{mn} + \tilde{E}_{mn} + \tilde{E}_{mp'} \left((Q^{-1} - 1) E^{-1} \right)^{p'q'} \tilde{E}_{q'n} \quad (3.15)$$

where

$$Q^{m'}_{n'} = \delta^{m'}_{n'} + M^{m'p'} E_{p'n'} , \quad (3.16)$$

and where E^{-1} denotes the inverse of $E_{m'n'}$.

In order to complete the picture we need to compute $\det L_{\mu\nu}$ and show that it equals $\det^{-1} Q$ in the physical gauge. This is a straightforward exercise using the $\exp \operatorname{tr} \ln$ formula for the determinant. For example, one has

$$\begin{aligned} \delta^{\mu\nu} E_{\mu\nu} &= \delta^{\mu\nu} \partial_\mu x^{m'} \partial_\nu x^{n'} E_{m'n'} \\ &= M^{m'n'} E_{m'n'} \\ &= -\operatorname{tr}(ME) \end{aligned} \quad (3.17)$$

in the physical gauge. One therefore obtains

$$\det L_{\mu\nu} = \exp(-\operatorname{tr} \ln(1 + ME)) = (\det Q)^{-1} \quad (3.18)$$

as required. So we indeed find that

$$\sqrt{-\operatorname{sdet} L_{MN}} = \sqrt{-\det (\tilde{E}_{mn} + F_{mn} + \tilde{E}_{mp'} [(Q^{-1} - 1)E^{-1}]^{p'q'} \tilde{E}_{q'n}) \det Q} . \quad (3.19)$$

It is quite remarkable that this expression agrees precisely with Myers's result [3] provided that one interprets it in the way we have suggested.

4 The Wess-Zumino term

In [3] Myers gives an expression for the WZ term for a Dp -brane modified to the non-abelian case. The most remarkable feature of this term is that p -branes can couple to higher-degree RR potential forms. The mechanism for this is that one can lower the degree of a pulled-back form by two by contracting a pair of transverse indices with $M^{m'n'}$, which is the commutator in Myers. In this way, for example, a five-form RR field can give rise to a three-form and thus couple to a D2-brane. However, it is far from obvious that Myers's WZ term is gauge-invariant or invariant under diffeomorphisms of the brane. In this section we construct a WZ term in our model which has these properties, although not manifestly. Its structure is very similar to the Myers WZ term, although the match up of the terms is not quite straightforward.

The Wess-Zumino term for a Dp -brane is

$$\mathcal{L}_{WZ} = \sqrt{N} \left[\exp(-\frac{1}{2} i_N) e^{\mathcal{F}} \sum \hat{C} \right]_{p+1,0} , \quad (4.1)$$

where $N := \det N^{\mu\nu}$. The subscript $(p+1, 0)$ indicates that the $(p+1, 0)$ -form component is to be projected out, a (p, q) -form being a $(p+q)$ -form on $\widehat{M}$ with even degree p and odd degree q in the hatted basis. The RR potentials $\hat{C}$ are pulled back to $\widehat{M}$ with the hatted pull-back, e.g.

$$\widehat{C}_{m\nu} = \mathcal{D}_m x^m \partial_\nu x^n C_{\underline{mn}} , \quad (4.2)$$

where

$$\mathcal{D}_m = \partial_m - K_m^\mu \partial_\mu . \quad (4.3)$$

The point of using this pull-back rather than the one defined with the straightforward gauge covariant derivative is that it is invariant with respect to the abelian gauge transformations of both $\mathcal{A}$ and B . The operation i_N appearing in (4.1) denotes the contraction of a form with $N^{\mu\nu}$. Again this is invariant under gauge transformations of $\mathcal{A}$ and B . However, the full expression is neither manifestly covariant under diffeomorphisms of $\widehat{M}$ nor under gauge transformations of the RR fields.

First suppose that the WZ form for a Dp-brane, divided by $\sqrt{N}$, transforms in a regular fashion, i.e. without a term involving $\partial_\mu \widehat{v}^m$, and let L be the dual of this form, then we can take the Lagrangian, regarded as a function, to be $L_{WZ} = \sqrt{N}L$, and we have

$$\delta L = (\widehat{v}^m \mathcal{D}_m + \widehat{v}^\mu \partial_\mu) L + \mathcal{D}_m \widehat{v}^m L \quad (4.4)$$

while

$$\delta \sqrt{N} = (\widehat{v}^m \mathcal{D}_m + \widehat{v}^\mu \partial_\mu) \sqrt{N} + \sqrt{N} K_{\mu\nu} (\widehat{v}^m N^{\mu\rho} \partial_\rho K_m^\nu - N^{\mu\rho} \partial_\rho \widehat{v}^\nu) . \quad (4.5)$$

Combining these two results it is easy to see that

$$\delta(\sqrt{N}L) = (-1)^M \partial_M (v^M (\sqrt{N}L)) . \quad (4.6)$$

We therefore see that if L transforms regularly then L_{WZ} will transform in the desired fashion under diffeomorphisms of $\widehat{M}$. The transformations of the pulled-back RR forms do include irregular terms and so the problem is to show that these all cancel between the different terms in the action involving the same RR field but different powers of i_N . In fact, we can use this to argue that these terms must be present. As a simple example, consider the C_3 terms in the action for a D2-brane. If we focus on only the irregular parts of the transformation of C_3 we have

$$\delta \widehat{C}_{mnp} \sim 3N^{\mu\nu} \partial_\nu \widehat{v}^q \mathcal{F}_{q[m} \widehat{C}_{|n|p]} \quad (4.7)$$

Clearly we need to add something to the Lagrangian proportional to N to cancel this variation. The obvious expression to try is $i_N \widehat{C} \mathcal{F}$, which involves the part of C with two fermionic indices. Since $\mathcal{F}$ has no fermionic indices, this term involves $\widehat{C}_{\mu\nu\rho}$. The irregular terms in the transformation of this field are

$$\delta \widehat{C}_{\mu\nu\rho} \sim 2\partial_{(\mu} \widehat{v}^q \widehat{C}_{|q|\nu)\rho} + N^{\rho\sigma} \partial_\rho \widehat{v}^q \mathcal{F}_{qp} \widehat{C}_{\mu\nu\sigma} . \quad (4.8)$$

The terms of interest in the transformation of $i_N \widehat{C} \mathcal{F}$ are therefore

$$\begin{aligned} \delta(N^{\mu\nu}\widehat{C}_{\mu\nu[m}\mathcal{F}_{np]}) &\sim N^{\mu\nu}N^{\rho\sigma}\partial_\rho\widehat{v}^q\widehat{C}_{\mu\nu\sigma}\mathcal{F}_{q[m}\mathcal{F}_{np]} \\ &+ 2N^{\mu\nu}\partial_\mu\widehat{v}^q\widehat{C}_{q\nu[m}\mathcal{F}_{np]} . \end{aligned} \quad (4.9)$$

The first line on the RHS vanishes as it involves $\mathcal{F} \wedge \mathcal{F}$ in three dimensions, while the second is equal to +2 multiplied by the RHS of (4.7). Expanding out the exponential in (4.1) we see that precisely the right coefficient is generated in order for these two terms to cancel. The remaining terms can easily be seen to be the regular terms in the transformation of the part of the D2-brane action which involves C_3 .

This line of reasoning can easily be extended to the general case. For a given brane, a given RR field will appear in a sequence of terms with increasing powers of $\mathcal{F}$ and i_N . It is not difficult to verify that the irregular variations in a given term cancel against those coming from the two adjacent terms. We can therefore conclude that the WZ term is invariant up to a total derivative under abelian gauge transformations of $\mathcal{A}$ and B and diffeomorphisms of $\widehat{M}$. Since the non-abelian gauge transformations arise from the vertical diffeomorphisms combined with the abelian gauge transformations of $\mathcal{A}$ in the standard gauge we are therefore assured that the WZ term will be invariant under these.

The above considerations indicate the need for the i_N terms but do not mix RR forms of different rank. The full structure is required by demanding gauge invariance for the background RR fields. Since the WZ Lagrangian is a sum of standard WZ terms of different rank one might think that this is obvious but closer inspection shows that it is not, because the i_N operation does not commute with exterior differentiation.

The proof of gauge invariance is not difficult however. We shall focus on the IIA case for simplicity. The gauge transformations of a $(p+1)$ -form potential is

$$\delta C_{p+1} = d\Lambda_p - \Lambda_{p-2}H \quad (4.10)$$

where H is the NS three-form, and Λ is used to denote the gauge parameters. Pulled back to $\widehat{M}$, H becomes $-dK$. So the gauge transformation of the WZ form is

$$\delta\mathcal{L}_{WZ} = \sqrt{N} \left[e^{-\frac{1}{2}i_N} \sum (d(\widehat{\Lambda}e^{\mathcal{F}}) + dN^{-1}\widehat{\Lambda}e^{\mathcal{F}}) \right]_{p+1,0} , \quad (4.11)$$

where

$$N^{-1} := K - \mathcal{F} \quad (4.12)$$

Now $\mathcal{F}$ is horizontal and is not acted on by i_N . It therefore plays no essential rôle in the proof that this expression gives rise to a total derivative. From this point of view it may as well be absorbed into the parameters Λ ; that is, we regard $\Lambda e^{\mathcal{F}}$ as the redefined Λ . Each Λ appears in pairs of terms which have the same degree. A general pair of terms in (4.11) has the form

$$\left(-\frac{1}{2}\right)^n \sqrt{N} \left(i_N^n (d\widehat{\Lambda})_{p+1,2n} - \frac{1}{2n+2} i_N^{n+1} (dN^{-1}\widehat{\Lambda})_{p+1,2n+2} \right) . \quad (4.13)$$

This gives the contribution of a $(2n + p)$ -form $\hat{\Lambda}$. We shall now show that this expression can indeed be written as a total derivative. The above formula suggests that it should be something like $d(\sqrt{N}i_N^n \hat{\Lambda})$ and we shall see that this is not far off the mark.

Let us introduce the notation $N^{\mu_1 \dots \mu_{2n}}$ to denote the symmetrised product of n N s. The first term in (4.13), ignoring the overall factor and the square root, is

$$\begin{aligned}
& N^{\mu_1 \dots \mu_{2n}} (d\hat{\Lambda})_{m_1 \dots m_{p+1} \mu_1 \dots \mu_{2n}} \\
&= N^{\mu_1 \dots \mu_{2n}} \left((p+1) \mathcal{D}_{m_1} \hat{\Lambda}_{m_2 \dots m_{p+1} \mu_1 \dots \mu_{2n}} - 2n \partial_{\mu_1} \hat{\Lambda}_{m_1 \dots m_{p+1} \mu_2 \dots \mu_{2n}} \right. \\
&\quad \left. - p(p+1) \mathcal{D}_{m_1} K_{m_2}{}^\rho \hat{\Lambda}_{m_3 \dots m_{p+1} \mu_2 \dots \mu_{2n} \rho} - 2n(p+1) \partial_{\mu_1} K_{m_1}{}^\rho \hat{\Lambda}_{m_2 \dots m_{p+1} \mu_2 \dots \mu_{2n} \rho} \right), \tag{4.14}
\end{aligned}$$

where antisymmetrisation over the free even indices is understood here and in the rest of the proof. The terms involving the derivatives of K arise because we are working in the horizontal lift basis. The second term in (4.13), again omitting the numerical factors and the square root, is

$$\begin{aligned}
& N^{\mu_1 \dots \mu_{2n+2}} (dN^{-1})_{[m_1 m_2 m_3 \hat{\Lambda}_{m_4 \dots m_{p+1} \mu_1 \dots \mu_{2n+2}]} \\
&= N^{\mu_1 \dots \mu_{2n+2}} \left(\frac{(2n+2)p(p+1)}{2} (dN^{-1})_{m_1 m_2 \mu_1} \hat{\Lambda}_{m_3 \dots m_{p+1} \mu_2 \dots \mu_{2n+2}} \right. \\
&\quad + \frac{(2n+2)!(p+1)}{2(2n)!} (dN^{-1})_{m_1 \mu_1 \mu_2} \hat{\Lambda}_{m_2 \dots m_{p+1} \mu_3 \dots \mu_{2n+2}} \\
&\quad \left. + \frac{(2n+2)!}{3!(2n-1)!} (dN^{-1})_{\mu_1 \mu_2 \mu_3} \hat{\Lambda}_{m_1 \dots m_{p+1} \mu_4 \dots \mu_{2n+2}} \right). \tag{4.15}
\end{aligned}$$

The exterior derivative of N^{-1} has the following non-trivial components

$$\begin{aligned}
(dN^{-1})_{m_1 m_2 \mu} &= 2 \mathcal{D}_{[m_1} K_{m_2]}{}^\rho K_{\rho \mu} \\
(dN^{-1})_{m_1 \mu_2 \mu_3} &= \mathcal{D}_{m_1} K_{\mu_2 \mu_3} - 2 \partial_{(\mu_2} K_{|m_1}{}^\rho K_{\rho|\mu_3)} \\
(dN^{-1})_{\mu_1 \mu_2 \mu_3} &= 3 \partial_{(\mu_1} K_{\mu_2 \mu_3)} . \tag{4.16}
\end{aligned}$$

We can group together like terms from the two original terms in (4.13) taking into account the relative numerical factor. It is easy to see that the terms involving $\mathcal{D}_m K_n{}^\rho$ cancel. Reinstating the square root of $\det N$ we see that the other terms with the derivative $\mathcal{D}_m$ can be written in the form

$$(p+1) \mathcal{D}_{m_1} (\sqrt{N} N^{\mu_1 \dots \mu_{2n}} \hat{\Lambda}_{m_2 \dots m_{p+1} \mu_1 \dots \mu_{2n}}) . \tag{4.17}$$

Next we consider the terms involving $\partial_\mu K_m{}^\rho$. The term of this sort in (4.14) is cancelled by one of the terms in (4.15) and we are left with

$$(p+1)\sqrt{N}N^{\mu_1\cdots\mu_{2n}}\partial_\rho K_{m_1}{}^\rho\hat{\Lambda}_{m_2\cdots m_{p+1}\mu_1\cdots\mu_{2n}} \quad (4.18)$$

The two expressions (4.17) and (4.18) combine to give

$$(p+1)\partial_{m_1}(\sqrt{N}(i_N^n\hat{\Lambda})_{m_2\cdots m_{p+1}}) + (p+1)\partial_\mu(\sqrt{N}K_{m_1}{}^\mu(i_N^n\hat{\Lambda})_{m_2\cdots m_{p+1}}) . \quad (4.19)$$

Finally, we consider the terms involving the fermionic derivative of $\hat{\Lambda}$ and N . After a short piece of algebra, and using the fact that $N^{\mu\nu}$ is the inverse of $K_{\mu\nu}$, one verifies that these give

$$-2n\partial_{\mu_1}(\sqrt{N}N^{\mu_1\cdots\mu_{2n}}\hat{\Lambda}_{m_1\cdots m_{p+1}\mu_2\cdots\mu_{2n}}) . \quad (4.20)$$

To conclude the proof, we can contract the above expressions, (4.19) and (4.20), with $\epsilon^{m_1\cdots m_{p+1}}$ to obtain total derivatives. We therefore conclude that the WZ term is indeed invariant, up to a divergence in $\widehat{M}$, under gauge transformations of the background RR potentials.

5 Comparison of WZ terms

The structure of our WZ term is clearly very similar to that of Myers's, but the way in which the various terms match up is not obvious since our inner product operation i_N involves the extra fermionic directions while Myers's involves the directions transverse to the brane in spacetime. In this section we shall prove that the two expressions agree precisely in the static gauge, given that we interpret our results as before.

The WZ term for a p -brane is

$$\mathcal{L}_{WZ} = \sqrt{N} \left[e^{-\frac{1}{2}i_N} e^{\mathcal{F}} \sum \hat{C} \right]_{p+1,0} \quad (5.1)$$

$\mathcal{F}$ is a $(2,0)$ -form which can be written, in the standard gauge (2.18), as¹

$$\mathcal{F}_{2,0} = F_{2,0} - \tilde{B}_{2,0} - b_{2,0} , \quad (5.2)$$

where

$$b_{mn} := \tilde{B}_{m\mu} N^{\mu\nu} \tilde{B}_{\nu n} . \quad (5.3)$$

The first two terms in $\mathcal{F}$ are very similar in our expression and in Myers's; since they are not seen by the i_N operation they can be absorbed into the RR potentials. With this understanding we can write the contribution of a $(p+1+2n)$ -form potential to the WZ term as

$$\begin{aligned} \mathcal{L}_{WZ} &\sim \sqrt{N} \left[e^{-\frac{1}{2}i_N} e^{-b_{2,0}} \hat{C}_{p+1+2n} \right]_{p+1,0} \\ &= \sqrt{N} \left[e^{-\frac{1}{2}i_N} \left(\hat{C}_{p+1,2n} - b_{2,0} \hat{C}_{p-1,2n+2} + \cdots \right) \right]_{p+1,0} . \end{aligned} \quad (5.4)$$

¹Throughout this section forms are written in the hatted basis ($e^m = dx^m, \hat{e}^\mu = d\eta^\mu + dx^m K_m{}^\mu$). Tildes refer to the components, e.g. $\tilde{B}_{1,1} = \hat{e}^\mu e^m \tilde{B}_{m\mu}$.

We shall prove the equivalence between this expression and the corresponding Myers term in steps. First we show that, in the standard gauge,

$$\left[e^{-\frac{1}{2}i_N} e^{-b_{2,0}} \hat{C}_{p+1+2n} \right]_{p+1,0} = \left[e^{-\frac{1}{2}i_N} e^{-\tilde{B}_{1,1}} \tilde{C}_{p+1+2n} \right]_{p+1,0} , \quad (5.5)$$

where $\tilde{B}_{1,1}$ has components $\tilde{B}_{m\mu}$. In order to prove this result we shall need to express $\hat{C}$ in terms of $\tilde{C}$, the Yang-Mills pulled-back potential. It is straightforward to see that

$$\hat{C}_{p+1,2n} = \sum_{q=0}^{q=p+1} \frac{1}{q!} (\tilde{B}_1^1)^q \tilde{C}_{p+1-q,2n+q} , \quad (5.6)$$

where $\tilde{B}_1^1$ denotes the vector-valued one-form with components $\tilde{B}_{m\nu} N^{\nu\mu} := \tilde{B}_m^\mu$.

We begin by looking at the terms with no b -field contributions. The term with q powers of $\tilde{B}$ on the LHS of (5.5) is

$$\left(-\frac{1}{2}\right)^n \frac{i_N^n}{q!n!} (\tilde{B}_1^1)^q \tilde{C}_{p+1-q,2n+q} , \quad (5.7)$$

whereas the RHS contribution comes from the term

$$\left(-\frac{1}{2}\right)^{n+q} \frac{(-1)^q i_N^{n+q}}{q!(n+q)!} \tilde{B}_{1,1}^q \tilde{C}_{p+1-q,2n+q} \quad (5.8)$$

Now

$$\begin{aligned} [\tilde{B}_{1,1}^q \tilde{C}_{p+1-q,2n+q}]_{m_1 \dots m_{p+1}, \mu_1 \dots \mu_{2n} \nu_1 \dots \nu_q \rho_1 \dots \rho_q} &= \epsilon_q (-1)^{q(p+1-q)} \frac{(p+1)!(2n+2q)!}{(p+1-q)!(2n+q)!} \times \\ &\times \tilde{B}_{[m_1(\nu_1 \dots \tilde{B}_{m_q \nu_q} \tilde{C}_{m_{q+1} \dots m_{p+1}]}]_{\mu_1 \dots \mu_{2n} \nu_1 \dots \rho_q}} \end{aligned} \quad (5.9)$$

where

$$\epsilon_q := (-1)^{\frac{1}{2}q(q-1)} . \quad (5.10)$$

In (5.8) the expression in (5.9) is to be contracted with $(n+q)$ powers of N . We can compute this by switching the symmetrisation brackets on the fermionic indices to N^{n+q} . To find the term with no b we then have to isolate the term in this expression of the form $N^{\mu_1 \dots \mu_{2n}} N^{\nu_1 \rho_1} \dots N^{\nu_q \rho_q}$. The result is

$$\epsilon_q \left(-\frac{1}{2}\right)^n \frac{i_N^n (p+1)!}{n!q!(p+1-q)!} \tilde{B}_{[m_1}^{\nu_1} \dots \tilde{B}_{m_q}^{\nu_q} \tilde{C}_{m_{q+1} \dots m_{p+1}]}_{\mu_1 \dots \mu_{2n} \nu_1 \dots \nu_q} , \quad (5.11)$$

and this is exactly equal to the component form of (5.7).

Now consider the terms with q powers of $\tilde{B}$ including b^r , where $q \geq 2r$. The LHS of (5.5) gives

$$\left(-\frac{1}{2}\right)^{n+r} \frac{1}{(q-2r)!} \frac{i_N^{n+r}}{(n+r)!} \frac{(-1)^r b^r}{r!} (\tilde{B}_1^1)^{q-2r} \tilde{C}_{p+1-q, 2n+q}, \quad (5.12)$$

We have to compare this with the b^r term in (5.8). Using the fact that $i_N(\tilde{B}_{1,1})^2 = 4b$, we find that this contribution to (5.8) is

$$4^r n_{r,q,n} \left(-\frac{1}{2}\right)^{n+q} \frac{(-1)^q}{q!} \frac{i_N^{n+q-r}}{(n+q)!} b^r \tilde{B}_{1,1}^{q-2r} \tilde{C}_{p+1-q, 2n+q}, \quad (5.13)$$

where it is understood that the remaining contractions do not give any more factors of b . The combinatoric factor $n_{r,q,n}$ is given by

$$n_{r,q,n} = \frac{q!(n+q)!}{2^r r! (q-2r)! (n+q-r)!}. \quad (5.14)$$

Using this in (5.13) and the previous result for no b terms one can easily verify that the LHS and RHS terms with b^r in (5.5) are indeed equal.

The second step is to show that

$$\sqrt{N} \left[e^{-\frac{1}{2} i_N \omega_{q,2n}} \right]_{q,0} = \left[e^{-\frac{1}{2} i_\delta e^{-B_{0,2}} \omega_{q,2n}} \right]_{q,0} \quad (5.15)$$

where i_δ means contraction with $\delta^{\mu\nu}$ instead of $N^{\mu\nu}$. The even part of the form ω does not play an essential rôle here, so we can take $q = 0$. In this case the LHS of (5.15) is

$$\sqrt{N} \frac{(-\frac{1}{2})^n}{n!} i_N^n \omega = \sqrt{N} \left(-\frac{1}{2}\right)^n \frac{1}{n!} \sum_{\{k\}} \omega(B^{k_1}, \dots, B^{k_n}), \quad (5.16)$$

where, on the RHS, ω is regarded as a symmetric n -linear map of symmetric matrices, $B(= B_{0,2})$ is regarded as a symmetric matrix, $(k_1, \dots, k_n)$ is an n -tuple of non-negative integers, and the sum is over all such n -tuples. B^{k_i} denotes the k_i th power of B as a matrix, with $(B^0)^{\mu\nu} = \delta^{\mu\nu}$. On the other hand, the RHS of (5.15) is

$$\sum_m (-1)^m \left(-\frac{1}{2}\right)^{n+m} \frac{i_\delta^{n+m} (B_{0,2}^m \omega)}{(n+m)! m!}. \quad (5.17)$$

Now

$$\iota_\delta^{n+m} (B_{0,2}^m \omega) = \sum_{\{k\}} \frac{2^k (n+m)! m!}{n! (m-k)! (m-k)!} \omega(B^{k_1}, \dots, B^{k_n}) \iota_\delta^{m-k} B_{0,2}^{m-k}, \quad (5.18)$$

where $k = \sum_{i=1}^n k_i$, and where the sum runs over all n -tuples such that $k \leq m$. Thus the RHS of (5.15) is

$$\sum_{m,\{k\}} \left(-\frac{1}{2}\right)^n \frac{1}{2^{m-k}[(m-k)!]^2} \omega(B^{k_1}, \dots, B^{k_n}) \iota_\delta^{m-k} B_{0,2}^{m-k} . \quad (5.19)$$

If we set $p = m - k$ we find that this is equal to

$$\left(\sum_p \frac{1}{2^p} \frac{i_\delta^p B_{0,2}^p}{(p!)^2} \right) \sum_{\{k\}} \left(-\frac{1}{2}\right)^n \frac{1}{n!} \omega(B^{k_1}, \dots, B^{k_n}) = \left[e^{-\frac{1}{2} i_\delta} e^{-B_{0,2}} \right]_{0,0} \sum_{\{k\}} \left(-\frac{1}{2}\right)^n \frac{1}{n!} \omega(B^{k_1}, \dots, B^{k_n}) . \quad (5.20)$$

It is not difficult to show that the factor in square brackets on the RHS of this equation is the square root of the determinant,

$$\sqrt{N} = \left[e^{-\frac{1}{2} i_\delta} e^{-\tilde{B}_{0,2}} \right]_{0,0} . \quad (5.21)$$

The use of this in (5.20) establishes (5.15).²

Finally, in the physical gauge,

$$(i_\delta^n) \omega_{p,2n} = (-i_M)^n \omega_{p,2n} \quad (5.22)$$

for any pulled-back form $\omega_{p,2n}$, where, on the right, $\omega_{p,2n}$ is a $(p + 2n)$ -form on the brane tangential degree p and normal degree $2n$. This is easy to see: suppose we have a $(0, 2)$ -form, $\omega_{0,2}$, then

$$\begin{aligned} i_\delta \omega_{0,2} &= \delta^{\mu\nu} \omega_{\mu\nu} \\ &= \delta^{\mu\nu} \partial_\mu x^{m'} \partial_\nu x^{n'} \omega_{m'n'} \\ &= M^{m'n'} \omega_{m'n'} = -i_M \omega . \end{aligned} \quad (5.23)$$

The proof can easily be extended to the general case. Combining all of these steps, and reinstating $\mathcal{F}$ we finally arrive at

$$\begin{aligned} \sqrt{N} \left[e^{-\frac{1}{2} i_N} e^{\mathcal{F}} \sum \hat{C} \right]_{p+1,0} &= \sqrt{N} \left[e^{-\frac{1}{2} i_N} e^{F - \tilde{B}_{2,0}} e^{-\tilde{B}_{1,1}} \sum \tilde{C} \right]_{p+1,0} \\ &= \left[e^{-\frac{1}{2} i_\delta} e^{F - \tilde{B}_{2,0} - \tilde{B}_{1,1} - \tilde{B}_{0,2}} \sum \tilde{C} \right]_{p+1,0} \\ &= \left[e^{\frac{1}{2} i_M} e^{F - \tilde{B}} \sum \tilde{C} \right]_{p+1,0} \end{aligned} \quad (5.24)$$

The final expression is the Myers WZ term which is only defined in the physical gauge. In the Myers term $\tilde{B}$ is the gauge-covariant pull-back of B . The equality between our WZ term and Myers's is to be interpreted in the same manner as for the DBIM part of the action.

²There is no difference between $\tilde{B}_{0,2}$ and $B_{0,2}$

6 Discussion

In this article we have argued that the action proposed by Myers for coincident D-branes in the physical gauge can be derived from a completely covariant formalism which makes use of boundary fermions. In order to make the final step from our results to Myers's we have to replace functions of η by matrices and replace integration over the fermionic variables by the symmetrised trace over matrices. This is quite natural as the boundary fermions have to be quantised when they are used to describe the Chan-Paton factors for the open string. In the standard gauge canonical quantisation leads to η^μ being replaced by γ^μ , so that functions of fermions naturally give rise to matrices. The path integral over the boundary fermions is designed to reproduce the path-ordered trace; if the integrand is local as a function of the parameter specifying the boundary of the string it is natural to interpret this as the symmetrised trace. It would nevertheless be preferable to justify this prescription in more detail from the worldsheet point of view, a topic we hope to report on in the future.

The main feature of our result is that the Myers action can be viewed as a gauge-fixed version of an action which is covariant under all the local symmetries. Although one would have expected this to be the case, it was not at all clear how the Myers action could be made compatible with these. Since the Myers action is defined in the physical gauge diffeomorphism invariance could not have been present, but invariance under gauge transformations of the background potentials was also rather obscure.

In [6] we used the boundary fermion formalism in the context of the open Green-Schwarz string to derive the equations of motion for a set of coincident supersymmetric branes in the classical limit, i.e. taking the fermions to be classical. Given the results of the present paper these equations should be equivalent to those one would derive from a supersymmetrisation of Myers's action. However, it is not easy to make the comparison because the Myers formalism is most suited to the action whereas the formalism of [6] leads naturally to equations of motion. It is not so easy to relate the two in such a complicated theory.

In [6] we used a supersymmetric extension of the formalism employed here, in the sense that the brane and the target space were taken to be superspaces, and in that context we also developed a manifestly covariant formalism. We then attempted to construct a covariant action form by generalising the construction of brane actions [11, 12] in the superembedding formalism [13, 14]. Although the details of this were not fully worked out the results derived in the present paper suggest that they could be. If so, this could be a much quicker and more transparent way of establishing covariance. A related topic, currently under investigation, is the construction of a kappa-symmetric Green-Schwarz action for coincident D-branes. It would also be interesting to compare the current approach with that of [15] where only a single kappa-symmetry is employed.

In conclusion, the current work suggests that the boundary fermion formalism could be very useful for discussing non-commutative aspects of coincident D-branes. Clearly further work needs to be done to put this approach on firmer ground. It would be interesting to see how it can be related to the work of various other groups, for example, on covariance, [16, 17, 18, 19], on higher-order terms via stable bundles [20], and on supersymmetry [21, 22, 23, 24, 25].

A Appendix

We briefly summarise our conventions for differential forms. We use superspace conventions. A p -form ω on $\widehat{M}$ is written

$$\begin{aligned}\omega &= \frac{1}{p!} e^{M_p} \dots e^{M_1} \omega_{M_1 \dots M_p} \\ &:= \frac{1}{p!} e^{M_p \dots M_1} \omega_{M_1 \dots M_p}\end{aligned}\tag{A.1}$$

where e^M is a set of basis one-forms. The components of ω are defined to be $\omega_{M_1 \dots M_p}$. The wedge product of two forms ω, ρ , both with even overall Grassmann parity, is

$$(\omega \wedge \rho)_{M_1 \dots M_{p+q}} = \frac{(p+q)!}{p!q!} \rho_{[M_1 \dots M_q} \omega_{M_{q+1} \dots M_{p+q}]} \ .\tag{A.2}$$

The exterior derivative acts from the right by

$$d\omega = \frac{1}{(p+1)!} e^{M_{p+1} \dots M_1} ((p+1) d_{M_1} \omega_{M_2 \dots M_{p+1}} - \frac{1}{2} p(p+1) f_{M_1 M_2}^N \omega_{N M_3 \dots M_{p+1}}) \ ,\tag{A.3}$$

where d_M denotes the vector fields dual to e^M and

$$[d_M, d_N] = f_{MN}^P d_P \ .\tag{A.4}$$

We have

$$d(\omega \wedge \rho) = \omega \wedge d\rho + (-1)^q d\omega \wedge \rho \ ,\tag{A.5}$$

where ρ is a q -form.

A vector-valued k -form,

$$L = \frac{1}{k!} e^{M_k \dots M_1} L_{M_1 \dots M_k}^N d_N \ ,\tag{A.6}$$

acts as a derivation of degree $k-1$ on forms by $\omega \rightarrow L\omega$ where

$$L\omega := \frac{1}{(k+p-1)!} e^{M_{k+p-1} \dots M_1} \frac{(k+p-1)!}{k!(p-1)!} L_{M_1 \dots M_k}^N \omega_{N M_{k+1} \dots M_{k+p-1}} \ .\tag{A.7}$$

If L is a vector, i.e. $k=0$, this formula reduces to the interior product of a vector with a p -form.

A (p, q) -form with respect to some splitting of the basis set into even and odd, $e^M = (e^m, e^\mu)$, is written

$$\omega = \frac{1}{p!q!} e^{\mu_q \dots \mu_1} e^{m_p \dots m_1} \omega_{m_1 \dots m_p \mu_1 \dots \mu_q} \ .\tag{A.8}$$

The operation i_N , where $N = N^{\mu\nu} d_\nu \otimes d_\mu$, is defined by

$$i_N \omega = \frac{1}{p!(q-2)!} e^{\mu_q \dots \mu_3} e^{m_p \dots m_1} N^{\mu_2 \mu_1} \omega_{m_1 \dots m_p \mu_1 \dots \mu_q} . \quad (\text{A.9})$$

If L is a vector-valued one-form of the form $L = e^m L_m{}^\mu d_\mu$ then

$$L\omega = \frac{1}{(p+1)!(q-1)!} e^{\mu_q \dots \mu_2} e^{m_{p+1} \dots m_1} (-1)^p (p+1) L_{m_1}{}^{\mu_1} \omega_{m_2 \dots m_{p+1} \mu_1 \dots \mu_q} . \quad (\text{A.10})$$

The sign $(-1)^p$ is explained as follows. L can be viewed as a one-form which starts acting from the right. It therefore has to be taken past p e^m s to act on e^{μ_1} . This where the sign comes from. It also acts on the other odd basis forms giving a factor of q . In the text we have used this operation with $L = \tilde{B}_1$ ¹.
